

Since the decade of the 50s until the 80s, public institutions from the Colombian government and private companies developed Uranium studies in the country without any production progress.

As a result of these studies, they have identified prospects in the country associated with sedimentary rocks (marine and continental origin) and igneous rocks distributed along the eastern and central mountain ranges - from the department of Huila to the department of Norte de Santander.

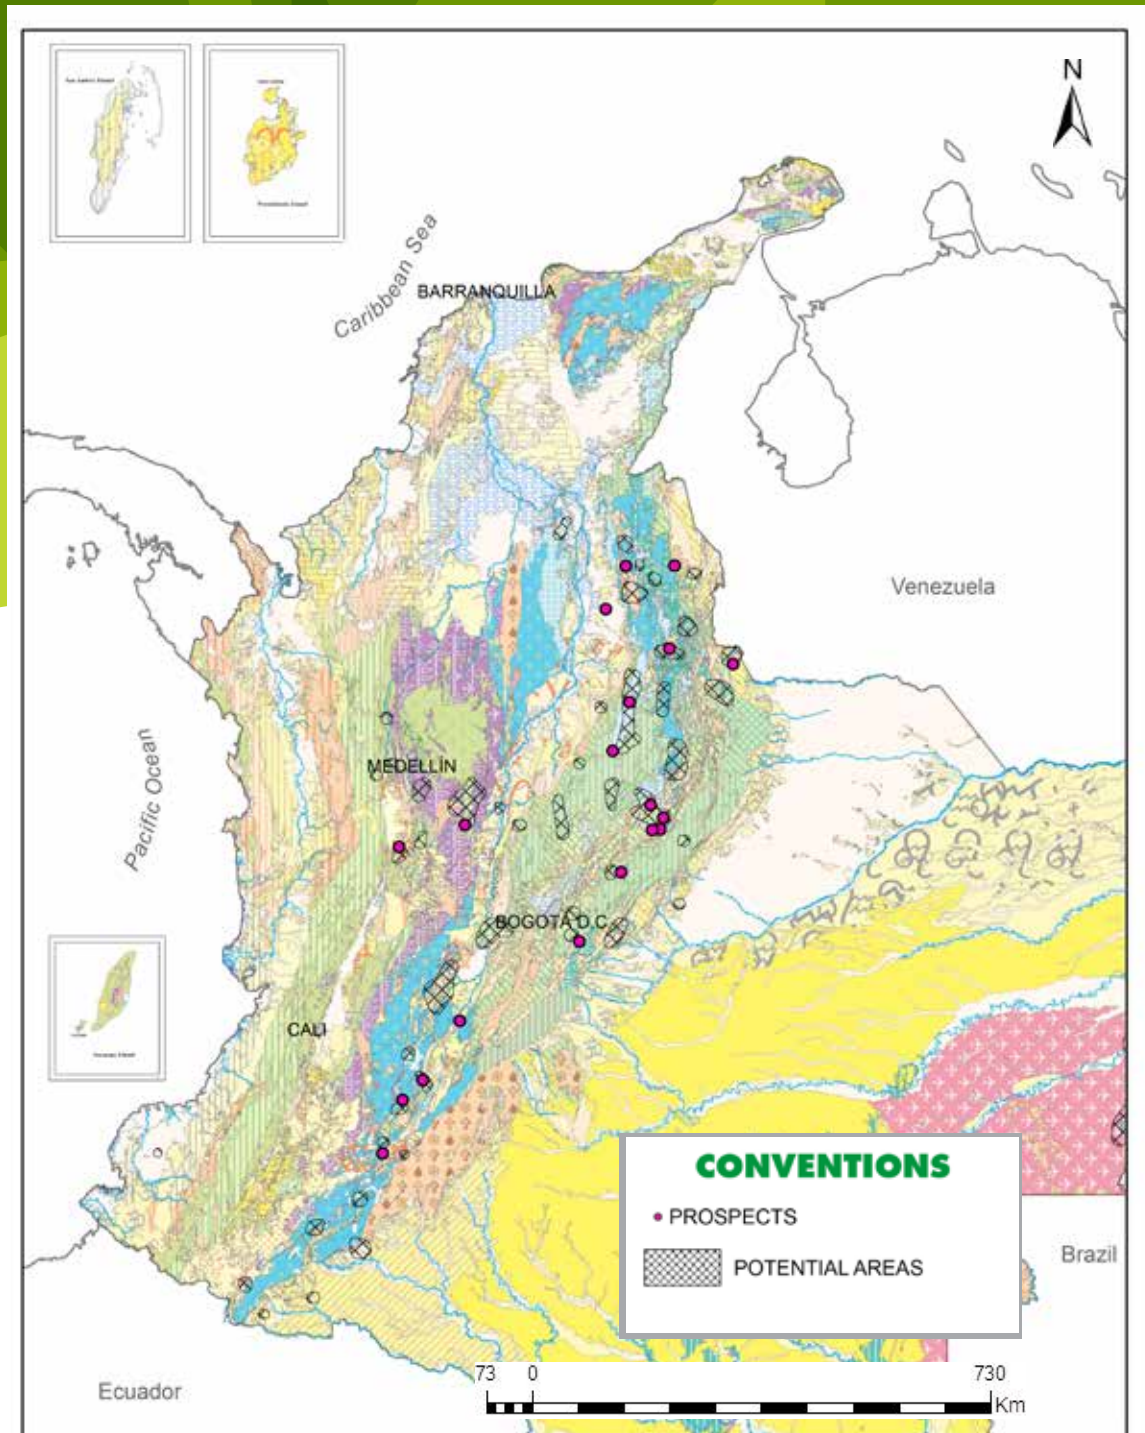

In recent years, with modern methods, multinational companies have made exploration campaigns in the area of Samana (eastern flank of the Central Mountain Range in the department of Caldas), rediscovering an ancient prospect. This type of exploration projects can open new perspectives in uranium exploration in Colombia.
